

Key Features of Common *Lygus* Species in the Central San Joaquin Valley

This handout should be used in conjunction with the detailed explanations and descriptions in **A Field Key to the Most Common *Lygus* Species Found in Agronomic Crops of the Central San Joaquin Valley of California** (UC ANR Publication 8104 at <http://anrcatalog.ucdavis.edu> or Lygus.uclac.edu)

The characteristics shown here best describe males of each species.

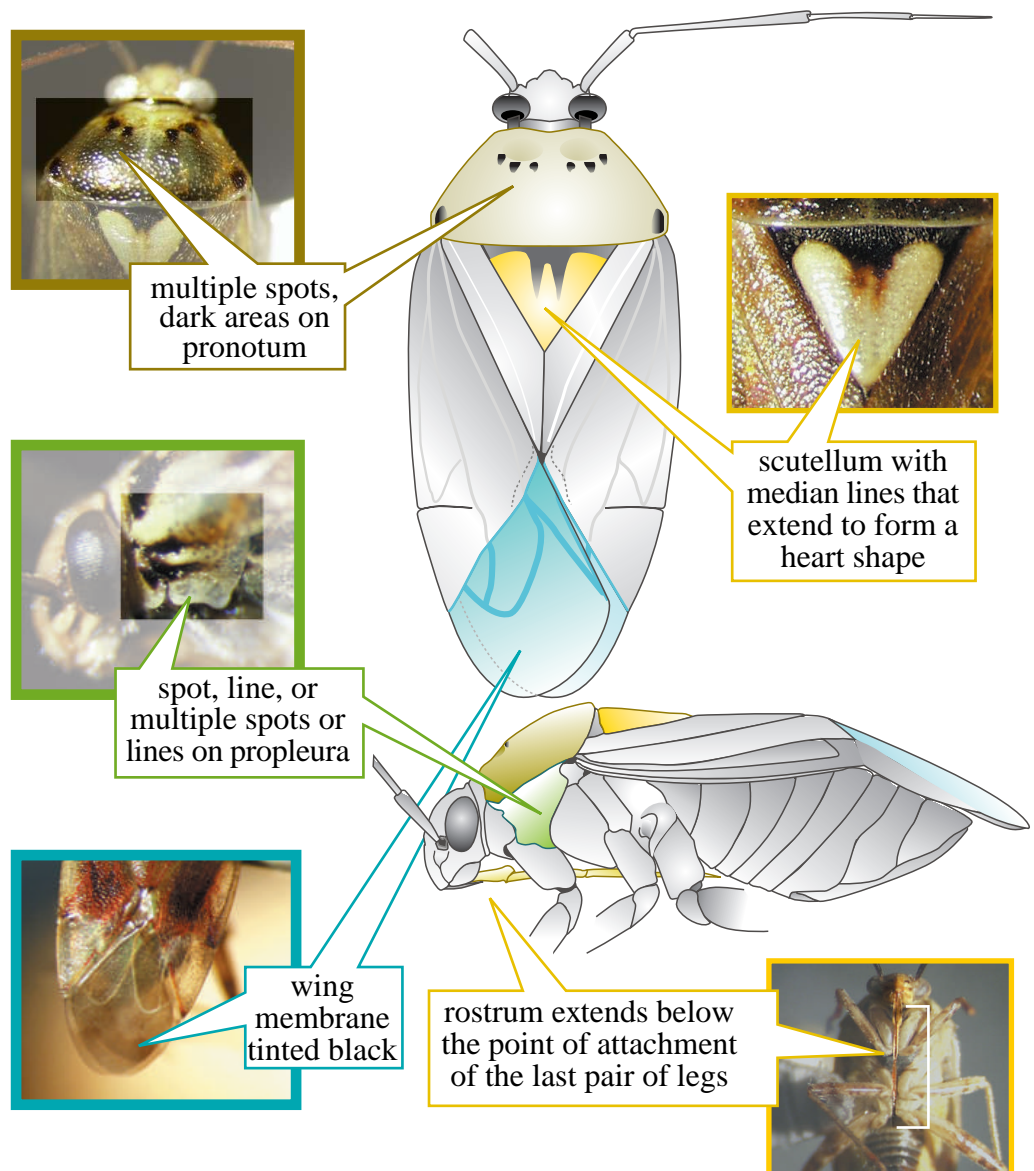

These species all have a **smooth** frons and **yellow** or **green** hind tibia. If your specimen does not exhibit these features, it is NOT one of the species identified in this publication.

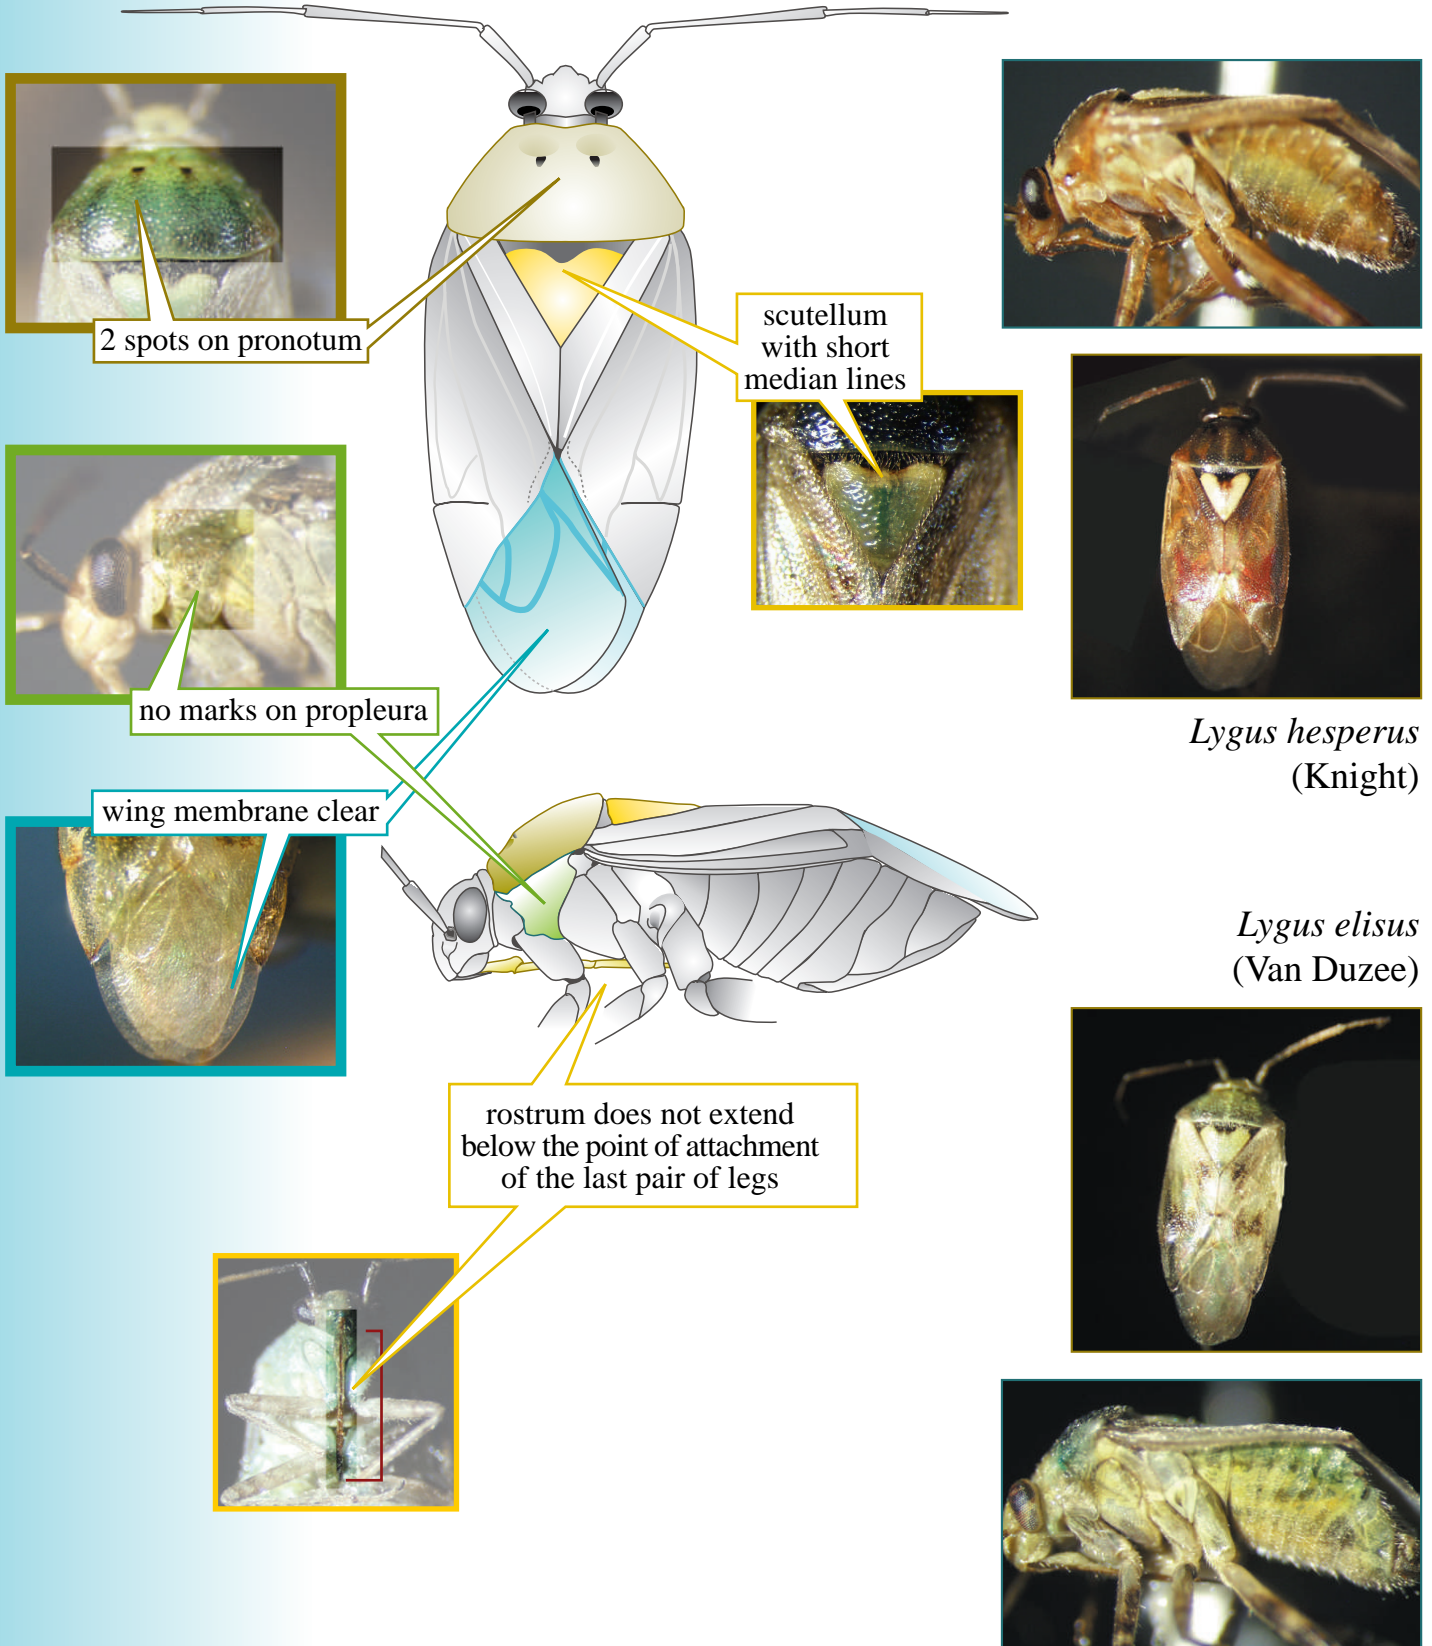

Publication 8105 is a “quick guide” that can be removed from the center of Publication 8104 and used independently once the user is familiar with key characteristics for distinguishing between species.

Examination of three characteristics will usually allow you to determine whether the specimen is *Lygus hesperus* or *Lygus elisus*. The characteristics are observed by examining the pronotum, the propleura, and the wing membrane. To confirm the initial identification based upon the three most reliable characteristics, examine the shape of the scutellum and the relative length of the rostrum.

Western Tarnished Plant Bug *Lygus hesperus* (Knight)

Pale Legume Bug *Lygus elisus* (Van Duzee)

Tarnished Plant Bug *Lygus lineolaris* (Palisot de Beauvois)

Lygus lineolaris is most easily characterized by the presence of submedian vittae on the frons, and yellow or reddish lateral margins on the mesoscutum. The scutellum has both median and lateral lines.

frons with submedian vittae

yellow or reddish lateral margins on the mesoscutum

median and lateral lines on the scutellum

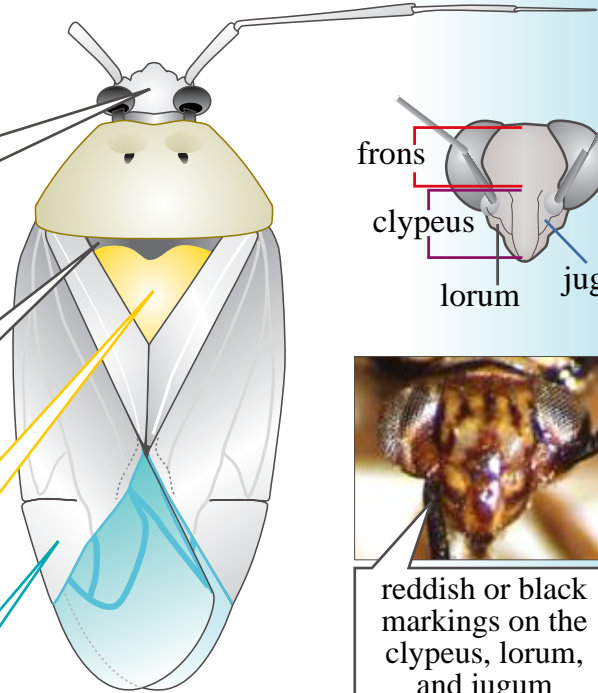

pale cuneus with a very large black apex

black spots, rays, and areas near the callus and base of the pronotum

dark lines on the propleura

reddish or black markings on the clypeus, lorum, and jugum

Lygus lineolaris
(Palisot de Beauvois)

Lygus Morphological Characteristics
